PREFACE

Initially, my thesis project was to set up Gulf General Atomic's multigroup neutron cross section code, GGC-4, on an IBM 7094 digital computer. I was to understand the theory used in the code, be able to operate the code well enough to document its operation for others (produce a local user's manual) and compile a source book of neutron group cross sections for weapons problems.

I obtained the GGC-4 code and the GGC-4 cross section library (data for 45 nuclides) from the Air Force Weapons Laboratory where a CDC 6600 digital computer was used to copy the code and the cross section library onto magnetic tapes. I was unable to program the GGC-4 code on the IBM 7094 due to what appeared to be insufficient computer memory, but with the possibility of it being due to a compatibility problem with the CDC 6600 output tape being used on the IBM 7094. I was eventually successful in obtaining data for the 45 nuclides from the GGC-4 data tapes.

My thesis advisor, Dr. C. J. Bridgman, and I decided to write our own code for the IBM 7094. This code calculates the zero moment of the neutron flux which is used to flux weight the GGC-4 cross section data. This code was the bulk of my thesis work. In the course of this work, I was able to obtain two new ENDF/B neutron cross section data tapes from Oak Ridge National Laboratory. I was able to use these ENDF/B data tapes with minor modifications to my original

moments code.

A few words should be said about the title of my code,
New Barnyard. The Resident School of Engineering at AFIT
has a cross section code called Old Barnyard that calculates
group cross sections for the energy range 10 MeV to thermal.
Old Barnyard's cross section library was updated by using
the cross section results from my code as the "new" input
library to Old Barnyard. Thus, the idea occurred to me of
calling my code New Barnyard.

I am indebted to several people in connection with this thesis: to my advisor, Dr. C. J. Bridgman, for guidance and counseling; to Lieutenant Robert Barry of the Air Force Weapons Laboratory, Kirtland, AFB, for help with the GGC-4 library tapes; to my classmates, Captains Jim Fisk and Robert Winchester, and Lieutenants Gary Knutson and Fred Damm, for many interesting discussions on transport theory, and to my typist, Mrs. Bobbie Thompson. Finally, I express special thanks to my wife, Cely, for her encouragement and good humor throughout my thesis study.

LIST OF SYMBOLS

The following mathematical symbols and nomenclature are used in this study.

SYMBOL	MEANING
D	Diffusion Coefficient, cm
ev	Electron Volts
E	Energy, ev
F [g(x)]	Fourier Transform of g(x)
N	Number density of the mixture, Atoms per barn-cm (atoms \times $10^{-24}/\text{cm}^3$)
P _n P ₁	Legendre Polynomials
R	Reaction rate, events/cm ³ -sec
S	Neutron source
x	Spatial dimension, cm
δ(x)	Dirac delta function
Θ_{o}^{o}	Zero moment of the neutron flux
$\Theta_{\mathrm{on}}^{\mathrm{P}}$	Pth derivative of the zero moment of the neutron flux in group n
LL.	Cosine of the scalar scattering angle
Ø	Microscopic cross section, barn
dΩ	Differential solid angle

NNUK

LIST OF SYMBOLS (Contd')

	did of dimbold (colled)
SYMBOL	MEANING
∑s (E → E, µo)	Macroscopic differential scatter- ing transfer cross section, cm ⁻¹ /steradian
$\sum_{\mathbf{sn}} (\mathbf{E}' \rightarrow \mathbf{E})$	Macroscopic scattering transfer cross section coefficient for scattering from energy E' to energy E associated with the n-th Legendre polynomial term in the expansion of the differential scattering transfer cross section, cm ⁻¹
$\sum_{\rm sn}(i{ ightarrow} j)$	Macroscopic scattering transfer cross section coefficient for scattering from group i to group j for the n-th Legendre polynomial term
PN (i→j)	PN scattering transfer cross section which is equal to $(2n + 1)*$ \sum_{sn} $(i \rightarrow j)$ with N=n.
(o)	Zero moment
$\Sigma_{ t tr}^{ t K}$	Macroscopic transport cross section for the K-th broad group
\sum_{a}^{K}	Macroscopic absorption cross section for the K-th broad group
\sum_{t}^{K}	Macroscopic total cross section for the K-th broad group
$\sum_{\mathbf{f}}^{\mathbf{K}}$	Macroscopic fission cross section for the K-th broad group

ABSTRACT

New Barnyard, a moments code, was written to calculate multigroup neutron macroscopic cross sections. Total, absorption, fission, and scattering transfer (group to group) cross sections can be calculated. The transport cross section, diffusion coefficient, and the average cosine of the scattering angle can also be calculated for each group. The energy range of these cross sections extends from 14.918 MeV to .4139 ev. Two versions of the moments code were written so that two different data sources could be used. With one version PO, P1, P2, and P3 elastic scattering transfer cross sections can be calculated for 22 broad groups, and with the other version PO through P8 elastic scattering transfer cross sections can be calculated for 20 broad groups.

New Barnyard was written in the Fortran IV language for use on an IBM 7094 digital computer. The code calculates the zero moment of the neutron flux which is then used to flux weight basic neutron cross section data over the energy limits of each group. Unlike some other moments codes, no first and second moments of neutron flux are calculated, and no B_L , P_L , age, or resonance calculations are performed. These calculations were excluded to achieve simplicity and speed of calculation. New Barnyard uses the GGC-4 cross section library as well as the new ENDF/B data from ORNL (Oak Ridge National Laboratory).

Excellent agreement was found when the results of New Barnyard were compared with results from other cross

ABSTRACT (Contd')

section codes. Results from the two versions of New Barnyard showed relative differences generally much less than
10% for comparisons between absorption and between total
cross sections. Larger relative differences were found in
the comparisons of the PN scattering transfer cross sections
due mainly to the fact that the number of terms used in the
Legendre polynomial expansion of the differential scattering
cross sections for each set of data on the two data tape
sources were different.

NEW BARNYARD: A MULTIGROUP NEUTRON CROSS SECTION CODE

I. Introduction

A need exists for multigroup neutron cross sections for weapons problems. Although many sets of group cross sections exist, most are based on reactor spectra and consequently are of limited use from about 2 to 15 MeV, the principle region of interest for weapon physics.

Purpose and Method

The purpose of this study is to produce a code that will calculate group neutron cross sections in this higher neutron energy range. The computer code described in this study calculates group neutron cross sections and related constants for the energy range .4139 ev to 14.918 MeV. It is written in Fortran IV and has been executed on an IBM 7094 computer. The cross sections are determined by first calculating the energy dependent flux in an infinite homogeneous mixture of the isotopes or compounds specified. This flux is then used to flux weight cross section data. The input cross section data is obtained from 99 group libraries of fast cross sections. The energy dependent flux is calculated by the method of moments.

Sequence of Development

The basic theory for the numerical equations used in New Barnyard is given in Chapter II. The cross section data tapes, the numerical equations, and the special output features of New Barnyard are presented in Chapter III. The

operating instructions for using New Barnyard on an IBM 7094 are given in Chapter IV. In Chapter V, results from other cross section codes are given and then the conclusions reached on the validity and accuracy of the code are stated.

II. Theory

In this chapter a brief review of the theory of flux weighting is given followed by a theoretical discussion of the calculation of the zero moment of the neutron flux which is used to flux weight cross sections in New Barnyard.

Flux Weighting

The reaction rate R (events/cm sec) in the presence of polyenergetic neutrons is

$$R = \int_{0}^{\infty} \phi(E) \sum_{i=1}^{\infty} (E) dE$$
 (1)

where E is the energy,

 ϕ (E) is the energy dependent flux in $_{0}^{1}/cm^{2}$ -sec,

 \sum (E) is the energy dependent macroscopic cross section in cm⁻¹.

The total flux is, by definition

$$\phi = \int_{0}^{\infty} \phi(E) dE$$
 (2)

In terms of this total flux, ϕ , the reaction rate can be written

$$R = \sum \phi$$
 (3)

where $\overline{\sum}$ is some average macroscopic cross section over the energy range of interest. It follows, by equating the reaction rates, i.e., the right hand sides of equations (1) and (3) and substituting from (2), that this average cross section must be given by

$$\overline{\sum} = 0 \frac{\int_{0}^{\infty} (E) \phi (E) dE}{\int_{0}^{\infty} \phi (E) dE}$$
(4)

or, in other words, the average cross section is a flux weighted average of the energy dependent cross section.

Equation (4) can be generalized to any range (limits on the integral), say from E_1 to E_2 , in order to produce an average cross section applicable to that energy range. Such averages are called energy group cross sections, and may be expressed as

$$\sum_{n}^{n} = \int_{E_{n}^{-}}^{E_{n}^{+}} \sum_{(E)} \phi (E) dE$$

$$\int_{E_{n}^{-}}^{E_{n}^{+}} \phi (E) dE$$
(5)

where $\sum_{i=1}^{n}$ is the group cross section for the n-th energy group,

 $\mathbf{E}_{n}^{\text{-}}$ is the lower energy boundary of the n-th group,

 E_n^+ is the upper energy boundary of the n-th group. From inspection of equation (5) it is seen that the variation of neutron flux with energy must be known in order to determine group cross sections.

Zero Moment of the Neutron Flux

The flux calculations performed in this code are in solution to the energy dependent Boltzmann transport equation for an above-thermal energy region (14.918 MeV to

.4139 ev). The energy dependent flux for this energy range is calculated by the method of moments. A brief review of the zero moment of the neutron flux will be discussed here. A more detailed analysis of the method of moments can be found in AFIT Technical Report 67-17 (Ref 1).

The steady state Boltzmann equation written for an infinite, non-multiplying homogeneous medium which scatters and absorbs neutrons is

$$\mu_{\frac{\partial \phi}{\partial x}}(x, E, \mu) + \sum_{t} (E) \phi(x, E, \mu) = S(x, E, \mu) + \int_{0}^{\infty} dE \sum_{s} (E' \to E, \mu_{o}) \phi(x, E', \mu')$$
(6)

Where X is the spatial positions of the neutrons

E is the neutron's energy,

- $\mu_{\rm o}$ is the cosine of the scalar angle, cosine $\theta_{\rm o}$, through which a neutron is scattered,
- μ or μ ' is the cosine of the scalar angle, cosine θ , (θ) between the neutron's direction and the X axis,
- $\phi(X,E,\mathcal{L})$ is the neutron flux in $_{o}n'/cm^{2}$ -sec-steradian-unit energy
- \sum_{t} (E) is the energy dependent macroscopic total cross section in cm⁻¹,
- $\sum_{s} (E' \rightarrow E, \mu_{o})$ is the energy dependent macroscopic differential scattering transfer cross section

for a neutron with an initial energy E' and an initial direction μ that scatters into a unit energy interval about E and within a unit solid angle about μ in cm⁻¹/steradian.

In the above-thermal energy region the target nuclei motion may be neglected with respect to the neutron energies. The moments method assumes that an isotropic source consisting of a plane of infinite area is located at the coordinate position x = 0, i.e.,

$$S(X,E,\mathcal{L}) = \frac{S(E)}{4\pi} \delta(X)$$
 (7)

Where $\mathfrak{G}(X)$ is the Dirac data function at X = 0. The flux in equation (6) is expanded in terms of Legendre polynomial as

$$\phi(X,E,\mathcal{L}) = \sum_{m=0}^{\infty} \frac{2m+1}{4\pi} \phi_m(X,E) P_m(\mathcal{L})$$
 (8)

Similarily, the differential scattering transfer cross section is expressed as

$$\sum_{s} (E' \to E, \mu_{o}) = \sum_{n=0}^{\infty} \frac{2n+1}{4\pi} \sum_{sn} (E' \to E) P_{n}(\mu_{o}) \qquad (9)$$

The coefficients, $\sum_{sn} (E' \rightarrow E)$, in the polynomial expansion in equation (9) are referred to as PN scattering transfer cross sections where PN is given by

$$PN(E' \rightarrow E) = (2n + 1) \sum_{sn} (E' \rightarrow E)$$
where N = n. (10)

The substitution of the source given by equation (7) and of the expansions (8) and (9) into equation (6) yields $\sum_{m=0}^{\infty} \left\{ \frac{2m+1}{4\pi} \frac{3\phi(x,E)}{2x} \mu_m^p(\mu) + \frac{2m+1}{4\pi} \sum_{t} (E) \phi_m(x,E) P_m(\mu) = \frac{S(E)}{4\pi} \delta(x) + \frac{S(E)}{4\pi} \delta(x) + \frac{S(E)}{4\pi} \sum_{t} (E' \to E) P_n(\mu_t) \right\} \left\{ \frac{2m+1}{4\pi} \phi_m(x,E') P_m(\mu') \right\}$

Equation (11) is simplified by using some of the special properties of Legendre polynomials (Ref 2: 115) to obtain

$$\sum_{m=0}^{\infty} \left\{ \frac{\partial \phi_m(X,E)}{\partial X} \left[(m+1) P_m(\mathcal{U}) + m P_m(\mathcal{U}) \right] + \right\}$$

$$(2m+1)\sum_{t}(E)\phi_{m}(X,E)P_{m}(\mathcal{U}) = S(E)\boldsymbol{d}(X) +$$

$$(2m+1)P_{m}(\mathcal{U}) \int_{0}^{\infty} dE' \sum_{sm}(E' \rightarrow E)\phi_{m}(X,E')$$
(12)

Equation (12), a single equation with an infinite number of terms, is transformed into an infinite number of coupled equations, each with a finite number of terms, by operating on equation (12), term by term, with

$$\int_{1}^{+1} (\mu) \langle eq.(12) \rangle d\mu \quad \ell=0,1,2,...$$
The results for $\ell=0$ are:

$$\frac{\partial \phi_{1}(X,E)}{\partial X} + \sum_{t} \phi_{0}(X,E) = \int_{0}^{\infty} \sum_{so} (E' \rightarrow E) \phi_{0}(X,E') dE' + S_{0}(E) \delta(X)$$
(13)

Equation (13) is the basis for the calculation of the zero moment of the neutron flux.

The basic energy dependence of the flux is expressed as the volume—angle integral of the flux, i.e.,

$$\bigoplus^{(o)} (E) = \int_{-\infty}^{+\infty} dX \int d\Omega \, \phi(X, E, \mathcal{L})$$
(14)

or integrating over $d\Omega$ to give

$$\bigoplus_{-\infty} (0) (E) = \int_{-\infty}^{+\infty} dX \phi_{O}(X, E) \tag{15}$$

where $\phi_0(X,E)$ is the all angle flux. Equation (15) is the zero moment of the spatial distribution of the total (all angle) flux. This "zero moment flux" can be calculated exactly by using some properties of the Fourier integral transform (Ref 3) on the spatial variable in equation (13), i.e.,

$$F\left\{ \oint_{\mathcal{L}} (X, E) \right\} = \int_{-\infty}^{+\infty} \oint_{\mathcal{L}} (X, E) e^{-ipx} dx = \oint_{\mathcal{L}} (P, E)$$
 (16)

It can be seen that if equation (16) is written for f(x) = 0 and the special case f(x) = 0, then it is equivalent to the zero moment of equation (15), i.e.,

$$\bigoplus_{O} (E) = \left[\theta_{O}(P, E) \right]_{P = 0}$$
(17)

Therefore, equation (13) is Fourier transformed using the properties (Ref 3)

$$F\left\langle \frac{\partial \phi_{O}(X,E)}{\partial X} \right\rangle = iP \theta_{O}(P,E)$$
 (18)

and

$$F\left\{ \mathbf{0}^{\bullet}(X)\right\} = 1$$

To obtain

To obtain

iP
$$\theta_1$$
 (P,E)= \sum_{t} (E) θ_0 (P,E)=S(E)+ $\int_{0}^{\infty} \sum_{so}$ (E'----E) θ_0 (P,E') dE'

(19)

Equation (19) is valid for any arbitrary P but from equation (17) the zero moment flux is obtained for P=0; therefore, Maclaurin expansions for θ_{Q} (P,E) and θ_{1} (P,E) are chosen as

$$\theta_{o}(P,E) = \theta_{o}^{o}(E) + (-iP)\theta_{o}^{1}(E) + (-iP)^{2}\theta_{o}^{2}(E) + \dots$$
 (20)

$$\theta_1(P,E) = \theta_1^0(E) + (-iP) \theta_1^1(E) + \frac{(-iP)^2}{2!} \theta_1^2(E) + \dots$$
 (21)

Where the argument of the Maclaurin expansion is (-iP) rather than P. The primes denoting differentiation in the expansion have been replaced by superscripts.

$$\theta''_{O}(E) = \theta_{O}^{2}(E)$$
 (22)

Under this notation the zero moment flux is symbolized

$$\bigoplus^{O}(E) = \theta^{O}_{O}(E) \tag{23}$$

Which is the energy dependent flux of interest.

Davison and Sykes, (Ref 4:343) show that the n-th moment of the neutron flux can only involve spherical harmonics of order n or less. Further they show that due to the odd-even nature of the functions involved

$$\int_{-\infty}^{\infty} x^{n} \phi_{L}(x,E) dx \neq 0$$
 (24)

only when both n and Lare both even or both odd. Thus the Maclaurin expansions become

$$\theta_{o}(P,E) = \theta_{o}^{o}(E) + (-iP)^{2} \theta_{o}^{2}(E) + \dots$$
 (25)

$$\theta_1(P,E) = (-iP)\theta_1^1(E) + (-iP)^3 \theta_1^3(E) + \dots$$
 (26)

By substituting equations (25) and (26) into equation (19) o and equating like powers of (-iP) the zero moment equation

is obtained
$$\sum_{t} (E) \theta_{o}^{O}(E) = S(E) + \int_{o}^{\infty} \sum_{so} (E' \rightarrow E) \theta_{o}^{O}(E') dE'$$
(27)

where $\theta_0^0(E)$ is the zero moment of the neutron flux and is the energy dependent flux necessary to calculate the group cross sections.

Solution of the Zero Moment Equation

Equation (27) is solved numerically by expressing it in multigroup notation. In group form it is

$$\int_{E_{n}^{-}}^{E_{n}^{+}} (E) \theta_{o}^{O}(E) dE = \int_{E_{n}^{-}}^{E_{n}^{+}} S(E) dE + \int_{E_{n}^{-}}^{E_{n}^{+}} \int_{O}^{\infty} (E' \rightarrow E) \theta^{O}(E') dE'$$
(28)

From the definition of a flux weighted group cross section, equation (5), it is seen that the first term becomes

$$\int_{E_{n}^{-}}^{E_{n}^{+}} \sum_{t} (E) \theta_{o}^{o}(E) dE = \sum_{t}^{n} \theta_{on}^{o}$$
(29)

Where \sum_{t}^{n} is the macroscopic total cross section of the n-th energy group, and θ is the total group flux. Similarly the second term is

$$\int_{E_{n}^{-}}^{E_{n}^{+}} S(E) dE = \chi_{n}$$
(30)

Where χ_n is the fraction of the source emitted in the n-th group, providing S(E) is a normalized source. The last term

$$\int_{E_{n}}^{E_{n}} dE \int_{0}^{\infty} \sum_{so} (E' \rightarrow E) \theta_{o}^{o}(E') dE'$$
(31)

is considered as a group of n double integrals where the integral from 0 to ω on dE' has been broken into n finite intervals; $\triangle E'_1$, $\triangle E'_2$, $\triangle E'_3$, ... over the energy range .4139 ev to 14.918 MeV. It is important that the integration on the variable E be performed first since the limits of integration on E, i.e., E_n^- to E_n^+ , are actually functions of E' and the maximum \triangle E of the scattering nucleus. The last term becomes

$$\int_{E_{n}}^{E_{n}^{+}} dE \int_{\Delta E_{1}^{'}} \sum_{so} (E' \rightarrow E) \theta_{o}^{o}(E') dE' +$$

$$\int_{E_{n}^{-}}^{E_{n}^{+}} dE \int_{\Delta E_{2}^{'}} \sum_{so} (E' \rightarrow E) \theta_{o}^{o}(E') dE' \dots \int_{E_{n}^{'}}^{E_{n}^{+}} dE \int_{\Delta E_{n}^{'}} \sum_{so} (E' \rightarrow E) \theta_{o}^{o}(E') dE' \dots \int_{E_{n}^{'}}^{E_{n}^{+}} dE \int_{\Delta E_{n}^{'}}^{E_{n}^{+}} dE \int_{\Delta E_$$

Each double integral, say the j-th, in equation (32) is a measure of the neutron scatter transport from the j-th to the n-th group. Recalling the definition of a flux weighted cross section in a slightly different form

ed cross section in a slightly different form
$$\sum_{so}(j\rightarrow n) = \int_{E_{n}}^{+} dE \int_{E_{j}}^{+} \sum_{so}(E'\rightarrow E)\theta_{o}^{o}(E')dE'$$

$$\int_{E_{j}}^{+} \theta_{o}^{o}(E')dE'$$

$$j$$
(33)

It is seen that equation (32) can be expressed as

$$\sum_{j=1}^{n} \sum_{so} (j \rightarrow n) \theta_{oj}^{o}$$
(34)

Substituting equations (29), (30), and (34) into question (28) and rearranging terms yields the numerical zero moment equation,

$$\left[\sum_{t}^{n} -\sum_{so}(n \rightarrow n)\right] \theta_{on}^{o} = \chi_{n}^{+} \sum_{j=1}^{n-1} \sum_{so}(j \rightarrow n) \theta_{oj}^{o}$$
(35)

The total group flux, θ_{on}^{o} , is determined by solving equation (35).

New Barnyard reads in a 99 group cross section set (or sets) from a cross section library tape, which is discussed in Chapter III, calculates a 99 group macroscopic cross section set, then flux calculation is begun with group one (highest energy group) where the scatter in term is zero. Calculation proceeds consecutively through all remaining groups down to .4139 ev. It is assumed that no "scatter up" in the neutron's energy occurs in this abovethermal energy region. Once the total flux has been calculated for each of the 99 groups, it is used to flux weight the 99 group macroscopic cross section set over each of the desired broad group limits.

III. The Code

In this chapter a few comments about New Barnyard are made followed by the contents and structure of the two data tape sources. Next, the numerical equations used to calculate the group cross sections and related constants are given and finally the special features of the output are mentioned.

New Barnyard is written in Fortran IV for an IEM 7094 digital computer. Two source decks are available in order to use the GGC-4 cross section data tape (Ref 5) and the two ENDF/B cross section data tapes (Ref 6). The GGC-4 source deck (i.e., the deck that uses the GGC-4 data tape) and the ENDF/B source deck are listed in appendices A and B. Extra comment cards have been positioned throughout the source decks to make them easier to read. Appendix C lists the variables and the meaning or use of each variable used in the two source decks. The code reads in cross section data and then determines the zero moment of the neutron flux which the code uses to calculate broad group cross sections and other related constants over the energy range .4139 ev to 14.918 MeV.

The Cross Section Data Tapes

As mentioned earlier, either the GGC-4 data tape or the ENDF/B data tapes can be used in New Barnyard. Both data tape sources have been compiled recently (1966-1967) and the results for absorption or total cross sections obtained from the two source decks for the same problem are within approximately 5 to 10% of each other. The ENDF/B data is updated from time to time by R.S.I.C. (The Radiation Shielding Information Center) at Oak Ridge National Laboratory. At this writing they are also preparing data for nuclides other than those that are contained on the ENDF/B data tapes described here. New data tapes can be obtained through R.S.I.C.*

Both data tape sources contain total, absorption, fission** and scattering transfer microscopic cross sections for 99 energy groups. The 99 "fine" group structure is shown in Appendix D. The PO transfer cross sections on the GGC-4 tape are listed separately as elastic, inelastic, n-2n, and total transfer. The ENDF/B tapes list only a PO transfer cross section which is the sum of the elastic, inelastic and 2(n-2n) transfer cross sections. The n-2n

** The ENDF/B data tapes list VO_f for 99 groups. The GGC-4 data tape list V and O_f separately.

^{*} ENDF/B data tapes are obtained from R.S.I.C, Oak Ridge National Laboratory, Post Office Box X, Oak Ridge, Tennessee, 37830

transfer cross section is multiplied by 2 to conserve neutrons. It is assumed that both neutrons are emitted in the same energy group. The GGC-4 tape has P0 through P3 elastic scattering transfer cross sections. The ENDF/B tapes have P0 through P8 elastic scattering transfer cross sections; however, the P0, as mentioned above, also includes inelastic and n-2n transfer cross sections. Both data sources include only P0 transfer cross sections for the n-2n and inelastic reactions. The GGC-4 tape also contains other information such as the 99 energy group boundaries, fission source spectrums, one dimensional cross section arrays (for (n,α) , (n,γ) and other similar reactions) and resonance data. The 99 group fission source spectrums for several nuclides are listed in Appendix F.

The GGC-4 tape has data for the following nuclides*:

- 1. Hydrogen
- 2. Deuterium
- 3. Helium
- 4. Lithium-6
- 5. Lithium-7
- 6. Beryllium

- 7. Boron (natural)
- 8. Boron-10
- 9. Carbon
- 10. Nitrogen
- 11. Oxygen
- 12. Sodium

^{*} It was mentioned that data for 45 nuclides was on the GGC-4 data tape; this is true but data for some nuclides is repeated. This repeated data was obtained by Gulf General Atomic from other sources.

Tables XIII and XIV show the structures of the data tapes and Table XV lists comments about these tapes. Appendix E contains these three tables.

Each of the 99 group cross section sets contained in the two data tape sources was calculated by flux weighting energy dependent cross sections with a 1/E flux dependence over the limits of each fine group. The specific calculations of these 99 group cross section sets can be found in the description of the GGC-4 code (Ref 5).

$$\mathcal{O}_{S}(E' \to E, \mathcal{H}_{o}) = \sum_{k=0}^{K} \frac{2n+1}{4\pi} \mathcal{O}_{sk} (E' \to E) P_{k}(\mathcal{H}_{o})$$
 (36)

These coefficients, $\mathcal{O}_{sk}(E' \rightarrow E)$, can be calculated by equating equation (36) to the experimental values of $\mathcal{O}_{S}(E' \rightarrow E, \mu_{o})$. The PN fine group scattering transfer cross sections are then calculated by weighting coefficients $\mathcal{O}_{sk}(E' \rightarrow E)$ with 1/E' over the limits of each fine group; that is,

$$PN(i \rightarrow j) = \frac{(2k+1) \int_{E_{i-1}}^{E_{i}} \int_{E_{j-1}}^{E_{j}} \int_{E_{i-1}}^{E_{j-1}} dE' dE}{\int_{E_{i-1}}^{E_{i}} \frac{dE'}{E'}}$$
(37)

$$k = 0, 1, 2, ...K$$

 $i = 2, 3, ... 99$
 $j = 2, 3, ... 100$

where N = k. This polynomial expansion of \mathcal{O}_S (E' \to E, \mathcal{H}_o) can lead to negative cross section values when the number of terms (K+1) used in the expansion is small. Thus, there is an advantage of having the ENDF/B data since it has P0 through P8 elastic scattering transfer cross section coefficients.

The Numerical Equations Used in the Code

After the code reads the 99 group set (or sets) of microscopic cross sections specified for a particular problem, it calculates a 99 group set of macroscopic cross sections using the relation

$$\sum_{i=1}^{n} = \sum_{i=1}^{NNUK} N_{i} O_{i}^{n}$$
(36)

where O_i is the microscopic cross section in barns for the i-th nuclide and the n-th fine group, N_i is the number density in nuclei/cm-barn for the i-th nuclide, NNUK is the

number of nuclides for the problem. The code then uses the fine group total macroscopic cross sections and the fine group PO total transfer macroscopic cross sections and calculates the total flux for each of the 99 groups from the zero moment equation (eq. (35)) which is repeated here for convenience:

$$\theta_{\text{on}}^{\text{o}} = \frac{1}{\left(\sum_{t=1}^{n} - \sum_{so} (n \rightarrow n)\right)} \left[\chi_{n} + \sum_{j=1}^{n-1} \sum_{so} (j \rightarrow n) \theta_{j}^{\text{o}} \right]$$

$$= 1, 2, 3, \dots 99$$
(35)

Next, the code flux weights the 99 group macroscopic cross section set over the limits of each of the broad groups. The specific cross sections calculated along with the numerical equations used to calculate them are listed below: (In the following equations, the subscripts n and j denote fine groups (any one of the 99 groups) and K and L denote broad groups.)

1. Absorption cross section

$$\sum_{a}^{K} = \frac{\sum_{n \in K}^{o} \theta_{on}^{o} \sum_{a}^{n}}{\sum_{n \in K}^{o} \theta_{on}^{o}}$$

$$K = 1, 2, 3, ... NBBG$$

2. Total cross section

$$\sum_{t}^{K} = \frac{\sum_{n \in K} \theta_{on}^{o} \sum_{t}^{n}}{\sum_{n \in K} \theta_{on}^{o}}$$

K=1, 2, 3, ...NBBG

Fission cross section 3.

$$\sum_{f}^{K} = \frac{\sum_{n \in K}^{K} \theta_{on}^{o} \sum_{f}^{n}}{\sum_{n \in K}^{n} \theta_{on}^{o}}$$

4. Nu* (Fission cross section)

$$(\mathcal{V} \sum_{f})^{K} = \frac{\sum_{n \in K}^{\infty} \theta_{on}^{o} \mathcal{V}^{n} \sum_{f}^{n}}{\sum_{n \in K}^{\infty} \theta_{on}^{o}}$$

$$K=1, 2, 3, ... NBBG$$

Scattering transfer cross section

$$PN(K \rightarrow L) = \frac{\sum_{n \in K}^{\infty} \theta_{on}^{o} \sum_{j \in L}^{\infty} PN(n \rightarrow j)}{\sum_{n \in K}^{\infty} \theta_{on}^{o}} K=1, 2, 3, ... NBBG$$

Where NBBG is the number of broad groups,

 θ_{on}^{o} is the total flux for the n-th group,

is the summation symbol denoting that the sum is $n \in K$ over all the fine groups in the broad group K,

- $\chi_{\rm n}$ is the fraction of the source neutrons emitted in the n-th group (source normalized to 1),
- \sum_{so} (j \rightarrow n) is the PO total scattering transfer macroscopic cross section for a neutron which scatters from group j to group n,
- \sum_{a}^{n} is the macroscopic absorption cross section for the n-th group,
- \sum_{t}^{n} is the macroscopic total cross section for the n-th group,
- \sum_{f}^{n} is the macroscopic fission cross section for the n-th group,
- is the average number of fission neutrons produced per fission event in the n-th group,
- PN(n \rightarrow j) is equal to (2N+1) \sum_{SN} (n \rightarrow j) where N=0, 1, 2, 3 for the GGC-4 data tape and N=0, 1, 2, ...8 for the ENDF/B data tapes,
- $\sum_{\mathrm{SN}} (\mathrm{n} \! o \! \mathrm{j})$ is the scattering transfer macroscopic cross section coefficient for a neutron which scatters from group n to group j. The subscript N denotes the N-th scattering transfer cross section coefficient (term) in the Legendre polynomial expansion of the differential scattering transfer cross section. For N=0, this can be the elastic,

inelastic, n-2n, or the total scattering transfer cross section when using the GGC-4 data tape but only the total scattering transfer cross section when using the ENDF/B data tapes.

The code also calculates the macroscopic transport cross section, the diffusion coefficient, and the average cosine of the scattering angle for each broad group. These three constants are defined as follows:

transport cross section,
$$\sum_{tr} = \sum_{t} - \sum_{si}$$

diffusion coefficient, $D = \frac{1}{3 \times \sum_{tr}}$
average cosine of the scattering angle, $\bar{\mu} = \frac{\sum_{si}}{\sum_{so}}$

The multigroup calculations performed in New Barnyard for these constants to obtain broad group constants are:

1. Transport cross section

$$\sum_{k=0}^{K} \sum_{k=0}^{K} \sum_{k$$

2. Diffusion coefficient

$$D^{K} = \frac{1}{3 \times \sum_{tr}}$$
 K=1, 2, 3, ...NBBG

3. Average cosine of the scattering angle $\frac{K}{\mu} = \frac{(P1(K \to K)/3)}{P0(K \to K)} K=1, 2, 3, ... NBBG$

Output Features of the Two Source Decks

Both source decks calculate total, absorption, and fission cross sections for each broad group as well as the transport cross section, diffusion coefficient, and the average cosine of the scattering angle for each broad group.

The ENDF/B source deck can also provide PO through P8 macroscopic elastic scattering transfer broad group cross sections; however, the PO transfer cross sections include inelastic and n-2n transfer cross sections as mentioned earlier. The order of the PN transfer cross sections desired is specified in the input data. The maximum number of broad groups is 20 due to the fact that insufficient core storage occurrs when more than 20 broad groups are used.

The GGC-4 source deck also provides a list of the nuclides on the data tape, the 99 fine group structure, the broad group structure, the PO elastic, inelastic, n-2n, and total transfer broad group cross sections, and it lists PO through P3 elastic scattering transfer broad group cross sections. This deck can calculate group cross sections for 22 broad groups.

IV. Operating Instructions

This chapter contains the information necessary to use New Barnyard (either source deck) on an IBM 7094 computer. The input data cards required for each source deck are given. Next, the control cards required by the IBM 7094 are shown, and finally the composite deck (control cards, source deck, data cards) is described.

The user should consider the following factors when selecting which source deck to use:

- 1. The GGC-4 source deck (i.e., the deck that uses the GGC-4 data tape) runs approximately twice as fast on the computer as the ENDF/B source deck.
- 2. Results for absorption or total cross sections from the two source decks for the same problem are approximately within 5 to 10% of each other.
- 3. P0 through P3 elastic scattering transfer cross sections can be obtained from the GGC-4 source deck PO through P8 elastic scattering transfer cross sections can be obtained from the ENDF/B source deck.
- 4. The PO output of the GGC-4 source deck lists separately the elastic, inelastic, 2(n-2n), and total transfer cross sections. The PO output of the ENDF/B source deck lists only the total transfer cross sections.

As a convenience to the user of New Barnyard, sample problems including input data cards and computer output from both source decks are presented in Appendix G.

Preparation of Input Data, Source Deck Using GGC-4 Data Tape

Preparation of Input I	data, source Deck Using GGC-4 Lata lape
CARD NUMBER 1:	Format (18A4)
Columns 1-72	Problem description - Anything can
	be punched on this card. This in-
	formation will appear at the top of
	each page of results.
Symbol*	BXCX(I), I=1, 18
CARD NUMBER 2:	Format (313)
Columns 1-3	The number of broad energy groups
Symbo1	NBBG, NBBG ≤ 22
Columns 4-6	The number of nuclides in the pro-
	blem
Symbo1	NNUK
Columns 7-9	This value is either 1 or 0. If it
	is 1, the code will calculate the
	flux. If it is 0, the code will
	have a flux input.
Symbol	KKK

^{*} The symbol (variable) used in the code for this specified data.

CARD NUMBER 3:

Format (2213)

Columns 1-3

Columns 4-6

etc.

boundaries are the numbers of the

Lower broad group boundaries-The

lowest fine group in each of the

selected broad groups. For example,

if one of the lower energy bounaries

was 10.00 MeV, the value 4 would be

specified. The number of values

punched on this card is equal to the

number of broad groups, NBBG.

Symbol

LBGB (I), I = 1, NBBG

Each of the actual energy boundaries selected for a particular problem must correspond to one of the 99 energy groups; therefore, the broad group boundaries should be selected from the 99 fine group structure (Appendix D).

Sometimes it is desirable to know the broad group scattering transfer cross section for scatter into a "thermal dump" group. This can be done in New Barnyard by specifying a broad group for the energy range .4139 ev to 0. The lower broad group boundary value that would be input for this group would be 100. This procedure is valid because both data sources give scattering transfer cross section values for scatter into this "100th" group; however, one should be aware of the fact that no 100th group total

or absorption cross section values are included on the data tapes.

CARD NUMBER 4: Format (1F12.7, 1E13.6)

Columns 1-12 Identification number of the nuclide

on the data tape - The I.D. number

for the nuclides are shown in Table I.

Symbol AID (IXL), IXL = 1, NNUK

Columns 13-25 The number density (nuclei/cm-barn)

of the nuclide

 $(\text{nuclei/cm-barn}) = \frac{\text{nuclei}}{\text{cm}^3} * 10^{-24} \frac{\text{cm}^2}{\text{barn}}$

Symbol DENT(IXL), IXL = 1, NNUK
Card 4 is repeated for each nuclide in the problem. All
card 4's precede card 5. It is necessary to start with the
card with the lowest I.D. number, followed by the cards with
increasing I.D. numbers, since the nuclides on the data tape
occur in the order of increasing I.D. numbers.

CARD NUMBER 5: Format (6E12.6)

Columns 1-12 Either a flux spectrum or a source

Columns 13-24 spectrum is specified depending on

• the value on card number 1 for KKK

etc. (columns 7-9). 99 values (6 per

card) must be specified.

Symbol FLUX (I) or SSSS(I), I=1,99

If a flux spectrum is included as input data, none of the values can be zero. Appendix F contains 99 group source spectrums for fissionable nuclides. The source spectrum used must be normalized to 1 as is the case for the spectrums in Appendix F.

Preparation of Input Data, Source Deck for ENDF/B Data Tapes

The first three input data cards are the same as the data cards for the GGC-4 source deck with the exception that the maximum allowable number of broad groups is 20 (i.e., NBBG-20).

Card 4 is repeated for each nuclide. All Card 4's precede Card 5. It is necessary to start for the card with the lowest material number followed by the cards with increasing material numbers, since the nuclides on each of the two data tapes occur in the order of increasing material number. If both data tapes are being used for a particular problem it is only necessary to have the cards arranged such that the material number (nuclides) that are on the same tape be placed in increasing order.

CARD NUMBER 4: Format (1x,1A4,2I2,1I6,1E13.4)

Columns 2-5 Material number of the nuclide on the data tape-The material numbers for the nuclides are shown in Tables II and III.

Symbol MATNO Columns 6-7 Order of the PN scattering transfer cross sections desired-The values allowed are 0 through 8. This value must be the same for each nuclide used in the problem. Symbol I.ORDER Columns 8-9 Logical unit number of the data tape-If using data tape B (Table II) the input value will be 1. If using data tape C (Table III) the input value will be 2. (No decimals are used with these values since I format) Symbol N Columns 10-15 The number of data records before reaching the nuclide of interest. Symbol NOR The number density (nuclei/cm-barn) Columns 16-28 of the nuclide $\frac{\text{nuclei}}{\text{cm-harm}} = \frac{\text{nuclei}}{3} * \frac{10^{-24} \text{cm}^2}{3}$

Symbol DENT

The number of data records before reaching the nuclide of interest is obtained with the aid of the "No. of data Records" columns in Tables II and III. For example, if C-12

and N-14 were the nuclides needed for a particular problem, the value 8886 would be punched on the data card for C-12, and the value 0 would be punched on the data card for N-14. When the computer reads the value 8886 it "skips" 8886 data records; that is, the data tape is advanced until the nuclide of interest is reached and then the computer begins to read the data from the tape. When the computer reads 0, no data records are skipped. If two nuclides of interest are separated by other nuclides, the number of data records that have to be skipped is the sum of the records for the nuclides separating the two. For example, if H-2, and Be were the nuclides of interest, 3068 (1537+1531) would be specified on the data card for H-2 and 0 would be specified on the data card for Be.

Control Cards for the IBM 7094

A brief explanation of the control cards used in the two source decks is given here to insure proper usage of these source decks on an IBM 7094 digital computer located at the Digital Computation Division (ASNCD), Wright-Patterson AFB, Ohio. As a convenience to the user, the only control card that will have to be prepared is the \$JOB card,

the first card of the composite deck; all other control cards have been prepared and positioned in the source decks. The user should be aware of the fact that control cards are subject to change and that each computer facility has its own characteristic control cards. The user should always have on hand the current literature for the computer being used.

Control Cards, GGC-4 Source Deck

The control cards used with the GGC-4 source deck are as follows:

Columns	1	8	16	31
	\$JOB \$SETUP \$IBJOB	1	Priority, Time, Lines OS122,NORING MAP,FIOCS	Job I.D.
	\$IBMAP	FILES ENTRY	.UN01.

Columns 1 8

\$IBFTC MAIN \$IBFTC REWE \$IBFTC ONEE \$IBFTC CSAVE \$DATA \$EOF

The \$JOB card is an orange card supplied by the computer facility. The priority number should always be 0 unless the user is authorized some other number. The time number is the estimated 7094 time* needed in minutes. The line number is the estimated number of lines** that will be output. This number should include all printing and card punching that will be done by the 7094. If either the time estimate or the line estimate is exceeded, the computer run will be terminated. The job identification should include the user's account number, office symbol, and name. After the user's name, there should appear a slash followed by the name Bridgman. The data tapes are filed under this name and it has to be present on the \$JOB card to use the GGC-4 data tape. An example of the \$JOB card is shown:

\$JOB 0,3,2000 68-564-00 AFIT-SE JONES/BRIDGMAN

^{*} An estimate of 3 minutes is usually adequate when using the GGC-4 source deck.

^{**} An estimate of 2000 lines is adequate for the GGC-4 source deck.

Control Cards, ENDF/B Source Deck

The control cards for the ENDF/B source deck are almost the same as the control cards for the GGC-4 source deck. The exceptions are the following:

- (1) No file is defined for logical unit 7 (only 3 scratch tapes are used)
- (2) 2 \$SETUP cards are used for the two input data tapes.
- (3) Usually an adequate time estimate for the \$JOB card is 5 minutes.

Composite Deck Setup

The composite deck setup for either source deck is shown below. The user has to supply the \$JOB card and the input data cards.

The \$SETUP Card is used to indicate the use of a data tape. The number 1 on this card refers to the logical number of the tape used in the program (GGC-4 Source deck). The number 0S122 is the number of the duplicate copy of the GGC-4 data tape. The word NORING that follows the tape number is used to indicate that the tape is not to be written on. The \$IBJOB card as used here is to have a print out (map) of the storage location of each variable used in the pro-The word FIOCS is used to cut down on the core storage requirement of the program. The \$IBMAP card and all the cards that follow up to and including the END card are used to define files for the input data tape and the 5 scratch tapes used by the program. The \$IBFTC cards are required for the main program and the subroutines used. The \$IBFTC MAIN card precedes the GGC-4 source deck and each of the other \$IBFTC cards precede a subroutine in the source deck. The names REWE, ONEE, and CSAVE that appear on these cards are arbitrary; any name (6 letters or less) other than the actual name of the subroutine can be used. The \$DATA card is required when input data cards are used. The \$EOF card is the end-of-file card and it is the last card of the composite deck.

V. Some Sample Results and Conclusions

In this chapter results of the GGC-4 version of New Barnyard are compared with results from other cross section codes; also, group cross sections calculated from the ENDF/B version of New Barnyard are compared with group cross sections calculated from the GGC-4 version. Throughout this chapter repeated reference will be made to the zero moment of the neutron flux, zero moment flux, energy dependent flux, and flux. These terms all mean the same thing. The reader is reminded that the GGC-4 version of New Barnyard refers to the source deck that uses the GGC-4 data tape and, the ENDF/B version of New Barnyard refers to the source deck that uses the two ENDF/B data tapes.

The Zero Moment of the Neutron Flux for Aluminum

It was pointed out in Chapter II that in order to calculate group cross sections, the energy dependent flux had to be known. This flux is obtained in New Barnyard by solving the zero moment equation (35). The validity of this flux calculation was checked by comparing New Barnyard's calculation of the zero moment flux for aluminum with Gulf General Atomic's GAM-1 (Ref 9) calculation of the zero moment flux for the same material. GAM-1 calculates group neutron cross sections and other related constants such as

age for the energy range 10 MeV to .4139 ev. GAM-1 uses a 68 group cross section library data tape. In order to have a better basis for comparison, the GGC-4 version of New Barnyard was modified slightly to use GAM-1's library data tape. Table IV shows the results of these two flux calculations. The ratio of the GAM-1 flux to the New Barnyard flux for each energy group is 4.000, as shown in Table IV. This indicates that the shape of the two flux spectrums are identical but with the GAM-1 flux having a magnitude 4 times larger than the New Barnyard flux. This factor of 4 is unimportant, however, since in the flux weighting process for the calculation of group cross sections this factor will always cancel and either flux will produce the same group cross sections.

Seven Group Cross sections for Carbon

The validity of the flux weighting process to calculate group cross sections was checked by comparing a 7 group macroscopic cross section set for carbon calculated by the GGC-4 version of New Barnyard with a 7 group macroscopic cross section set for carbon calculated by the GGC-4 code. The GGC-4 code was run on a CDC 6600 computer at the A.F. Weapons Lab. The same flux spectrum was input to each of the codes. The group cross sections obtained from each of the codes were exactly identical. Table V shows

the broad group structure for this cross section set. Table
VI shows the results from both codes for the total cross
sections and Table VII lists the PO (total transfer)
scattering cross sections from both codes.

Six Group Cross Section Set for Nitrogen

A comparison of cross sections calculated in the ENDF/B version of New Barnyard and the GGC-4 version of New Barnyard was made for several problems. The 6 group cross section set for nitrogen that is presented here for comparison is typical of the cross section comparisons obtained for other nuclides and mixtures. The cross sections calculated by the GGC-4 version of New Barnyard were used as the standard for the relative difference calculations between these two cross section sets. Table VIII shows the 6 group structure of the cross sections. The absorption cross sections obtained from the two versions of New Barnyard and the relative differences between these cross sections are shown in Table IX; similarly, Table X shows the total cross sections and their relative differences. Table XI and XII show the comparisons for the PO, P1, P2, and P3 scattering transfer cross sections. The P0 cross section is the total transfer cross section which is the sum of the elastic inelastic, and 2 (n-2n) transfer cross section. The P1 through P3 cross sections are elastic scattering cross sections only.

By inspection of Tables $\dot{}$ IX and $\dot{}$ X it is seen that the largest relative differences are 13% and 14% which

occurred for the 3rd and 4th group absorption cross sections respectively. Even these relative differences aren't too great when one considers the following factors:

- (1) The cross section data tapes are from two independent sources, namely GGA (Gulf General Atom) and ORNL (Oak Ridge National Lab.).
- (2) Each group flux is dependent on the total and PO fine group cross sections. If there exists a relative difference for each group cross section, then there exists a relative difference for each group flux. Since broad group cross sections are obtained by flux weighting fine group cross sections, it is logical to argue that the relative differences build up rapidly since when multiplying or adding variables that have relative differences (errors) associated with them these relative differences are added together.

The comparisons of the PO scattering transfer cross section are quite good. Table XI shows that most relative differences are less than 5%; however, the relative differences for the PO cross sections for transfer from 1 to 3, 1 to 4, 1 to 5, and 1 to 6, were 41, 99, 100, and 100%

respectively, but these four cross section values are very small in magnitude and most likely ORNL did not list cross section values as small as GGA's. The largest relative difference in the comparisons between the P1 cross sections was 21%. It is seen from Table XII that the relative differences in the comparisons between P2 cross sections are good except for cross section values for transfer from 1 to 1 and 1 to 2. Note that in the P3 cross section comparison, even larger relative differences than for P2 are common and that for 3 of the cross section comparisons (denoted by an asterisk) the algebraic signs differ between the cross sections. All of these large relative differences and alternating algebraic signs can be explained by the fact that ORNL used an 8th order Legendre polynomial expansion of the fine group differential scattering transfer cross sections and GGA used a 6th order *Legendre polynomial expansion.

^{*} GGA only listed PO through P3 cross sections on the GGC-4 data tape.

Conclusions

The comparison of the flux calculated by New Barnyard with the flux calculated by GAM-1 and the comparison of the group cross sections calculated by New Barnyard with the group cross sections calculated by GGC-4 give confidence in the "correctness" or validity of the calculations performed by New Barnyard; that is, New Barnyard does what it is supposed to do, and does it right. Some thought, however, should now be given to the usefulness of the zero moment of the neutron flux for flux weighting cross sections.

Recall that the zero moment equation was based on an infinite medium and a plane source of infinite dimensions at the origin. Assumptions such as these are valid for reactor calculations where one at least crudely has a plane source (fission neutrons in the core) and an infinite medium (shielding around the core). When considering one dimensional thin shield transport calculations for neutrons with energies above thermal, where the mean free path of a neutron is larger than the thickness of the shield, the zero moment equation leads to an inaccurate flux spectrum. Thus, for a thin shield calculation a better approximation for the flux is one equal to the source spectrum for the problem since relatively few neutrons are slowed down when passing through the shield. It was for cases such as this that

New Barnyard was programmed with the option of inputting a flux spectrum.

One should also recall that no resonance calculations are performed in New Barnyard; however, resonances in general are negligible above a few kev and it is above this energy range that New Barnyard is primarily intended.

Finally, recall the zero moment flux was used to flux weight PO through P8 scattering transfer cross sections. Cross section codes such as GAM-1 and GGC-4 usually flux weight the PN cross sections with a corresponding $\Phi_{\rm N}$ flux which comes from the expansion of the three dimensional flux, Φ (X, E, μ), in a Legendre polynomial series followed by either a B_L (Ref 10) or a P_L (Ref 11) solution to the Boltzmann equation. In general, as N becomes large $\Phi_{\rm N}$ becomes small; thus, flux weighting the PN cross sections with $\Phi_{\rm N}$ fluxes produces PN group cross sections smaller than the corresponding PN group cross sections flux weighted by the zero moment flux.

APPENDIX A

GGC-4 Source Deck of New Barnyard

On the following pages is listed the source deck that uses the GGC-4 cross section library data tape. It is written in the Fortran IV language for use on the IBM 7094 digital computer. It consists of a main program and 3 separate subroutines.

Input data from data cards and from the GGC-4 cross section data tape are "read in" in the main program. Five scratch tapes are used to store PO, P1, P2, P3, inelastic, n-2n, and total PO cross section arrays until they are needed in the main program. The flux calculation and the broad group calculations of the transport cross section, diffusion coefficient, and the average cosine of the scattering angle are performed in the main program.

The subroutine named REW is used to rewind the scratch tapes and to set a double subscripted scattering transfer cross section symbol to zero. The subroutine named ONE is used to calculate 99 group macroscopic transfer cross section sets. The subroutine named CSAV is called in the main program to flux weight the cross sections.

Extra comment cards have been added to the listing that follows so that the program will be easier to read. A glossary of computer program symbols is given in Appendix C.

APPENDIX B

ENDF/B Source Deck of New Barnyard

On the following pages is listed the source deck that uses the two ENDF/B data tapes. It is written in the Fortran IV language for use on the IBM 7094 digital computer. It consists of a main program and 4 separate subroutines.

Input data from data cards is "read in" in the main program. The cross section data required for the problem is obtained in the subroutine named FIB which reads the data from the data tape. Three scratch tapes are used to store the PN scattering transfer cross sections until they are needed in the main program. The flux calculation, and the broad group calculations of the transport cross section, diffusion coefficient, and the average cosine of the scattering angle are performed in the main program.

The subroutines named REW, ONE, and CSAV perform the same calculations as the subroutines with the same names in the GGC-4 source deck. These subroutines were discussed briefly in Appendix A.

Extra comment cards have been added to the listing that follows so that it will be easier to read. A glossary of computer program symbols is given in Appendix C.

Glossary of Computer Program Symbols

The following Fortran IV nomenclature is used in both source decks of New Barnyard. The program themselves are listed in Appendices A and B.

Symbol	Meaning or Use
A(I)	: Alphameric variable* for tempor- ary storage of information concern- ing cross section data for a nuclide
ABBS (I)	: Absorption cross section for the I-th broad group
AID(IXL)	: Nuclide I.D. number for the IXL-th nuclide
AT(I)	: Alphameric variable used for data tape description
B(K)	: Single array variable used for the temporary storage of cross section data
BUM	: Summing Variable
BXCX(I)	: Alphameric variable used for problem description
C1	: Alphameric variable used to check alphameric data from the data tapes
CSAV	: Subroutine that flux weights fine group cross sections

^{*} Alphameric variable refers to a variable which is "read in" under an A format.

Symbo1	Meaning or use
D(I)	: Diffusion coefficient for the I-th broad group
DAD(I)	: Alphameric variable used for nuclide description
DD(1, IXL)	: Nuclide I.D. number of the IXL-th nuclide
DD(2, IXL)	: Resonance parameter of the IXL-th nuclide
DD(3,IXL)	: Resonance parameter of the IXL-th nuclide
DENT(IXL)	: Number density of IXL-th nuclide
DUMMY	: The first variable of a data record
ENG(I)	: Convenience variable for temporary storage of the i-th fine group boundary and also the i-th fine group average number of neutrons emitted per fission event
ESS(I)	: Alphameric variable used for nuclide description
F, FF	: Summing variables
FIB	: Subroutine used to read the ENDF/B data tapes
FLUX(I)	: Neutron flux for the I-th fine group
FNBT	: Data tape number on the GGC-4 data tape
FTOT(I)	: Fission cross section for the I-th broad group

Ар	pendix C (Contd)
Symbo1	Meaning or Use
FPL	: Convenience variable for problem constant
GTH(I)	: Energy boundary of the I-th ther- mal fine group
ID	: Convenience variable used as an identification number for a particular set of data
III	: Fine group number
IS, IX, I	: Summing variables
ISI	: Convenience variable for a pro- blem constant
ITSN	: Logical unit number of scratch tape
J2	: Convenience variable for a pro- blem constant
JNVN, JNY, JNYY	: Broad group numbers
JY, JT	: Convenience variable for problem constant
KK	: Convenience variable for desig- nating the KK-th dimension of a di- mensioned variable and also used for a fine group number
KKK	: Indicator for performing a flux calculation or inputting a flux spectrum
KKKK	: Convenience variable for tempor- ary storage of a fine group number
LBS	: Convenience variable for problem

constant

Symbol Meaning or Use

LD : Number of fine groups scattered

to

LDF : Number of fine groups scattered

from

LEN(I) : I-th resonance parameter

LLBBG(I), LBGB(I) : Lower broad group boundaries of

the I-th group

LNX : Length of I-D cross section array

LORDER : Order of the PN scattering trans-

fer cross section

LORI : Convenience variable for problem

constant

LPC, LRINK : Summing variables

LT : Length of cross section array

M(K) : Convenience variable used for

temporary storage of cross section

data

MATNO : Material number of a nuclide

MODE : Convenience variable for problem

constant

MG : Logical unit number of GGC-4

data tape

MM : Convenience variable for tempor-

ary storage of a fine group number

MMMT, MMT, MSS, MT,

MTT : Logical unit numbers of scratch

tapes

N : Logical unit number of ENDF/B

data tape

NA : Summing variable

NB : Convenience variable used for

temporary storage of a fine group

number

NBBG : Number of broad groups for a

particular problem

NBT : Data tape number on the GGC-4

data tape

NBTC : Data tape number on the GGC-4

data tape

NEP : Number of fine group energy

boundaries

NES : Convenience variable for pro-

blem constant

NEV : Number of fine groups

NGP, NGP3 : Convenience variable for pro-

blem constant

NGT : Number of thermal energy boun-

daries

NMORE : Number of records that contain

resonance data

NNOT : Number of nuclides for which

data is listed on the GGC-4 data

tape

NNNN : Convenience variable used for

temporary storage of a fine group

number

Symbol Meaning or Use

NNUK : Number of nuclides for a parti-

cular problem

NOR : Number of data records

NPRf : Convenience variable for problem

constant

NRK : Number of data records for a

nuclide

NSP : Number of fission sources on the

GGC-4 data tape

NT : Convenience variable for problem

constant

NTCH1, NTCH2 : Logical unit number of scratch

tapes

NTID(I) : Convenience variable used for

temporary storage of miscellaneous

data from the GGC-4 data tape

NX : Number of I-D cross section

arrays for a nuclide

ONE : Subroutine for calculating mac-

roscopic scattering transfer cross

sections

P0(LL,I) P1(LL,I),

P2(LL,I), P3(LL,I) : Convenience variables used for temporary storage of PN scattering

transfer cross section for scattering transfer cross section for scattering from broad group LL to

broad group I

REW : Subroutine used for rewinding

scratch tapes and setting a two dimensional scattering transfer cross section variable to zero

Symbo1	Meaning or Use
SIGA (I)	: Absorption cross section for the I-th fine group
SIGT (I)	: Total cross section for the I-th fine group
SIGQ (I)	: Fission cross section for the I-th fine group
SIGTR (I)	: Transport cross section for the I-th broad group
SISO(LL,I)	: Total PO scattering transfer cross section for scattering from broad group LL to broad group I
SS(I)	: Convenience variable used for temporary storage of specific data for a nuclide
SSS	: Nuclide I.D. number
SSSS(I)	: Convenience variable used for temporary storage of the source spectrum and also the fission cross section times Nu.
SUM, SUMM, SUMMM	: Summing variables
TEMP (K)	: Convenience variable used for the temporary storage of cross sec- tion data
TTT(I)	: Total cross section for the I-th broad group
TRA(I)	: Convenience variable for temporary storage of energies and lethargies

Symbo1	Meaning or Use
TT(K,KK)	: Scattering transfer cross section for scatter from fine group K to fine group KK (GGC-4 source deck)
TT(K,KK)	: Scattering transfer cross section for scatter from fine group J to fine group KK where K is equal to KK+4-J (ENDF/B deck)
TT(3,1)	: Total cross section for the I-th fine group (ENDF/B deck)
TT(2,1)	: Fission cross section times Nu for the I-th fine group (ENDF/B deck)
TT(1,1)	: Absorption cross section for the I-th fine group (ENDF/B deck)
TTT(I)	: Convenience variable used for temporary storage of cross section data and resonance data
XINELAS(LL,I)	: Inelastic scattering transfer for cross section for scatter from broad group LL to broad group I
XMUBAR(I)	: Average cosine of the scattering angle for broad group I
XN2N(LL,I)	: N-2N scattering transfer cross section for scatter from broad group LL to broad group I

APPENDIX D

The 99 Fine Group Structure

On the following pages are listed the 99 fine group boundaries and the corresponding 99 group lethargies used in both versions of New Barnyard. The 99 group structure is calculated as follows:

Let ${\bf E}_5$, the fifth energy point, be equal to 10 MeV and let it be the reference energy. Therefore,

$$E_5 = 10^7 \text{ ev}$$
 (D1)
 $U_5 = 0$

The first energy point is taken to be $E_1=E_5$ e^{-(-.4)}. The next 49 points are determined with a uniform lethargy mesh U=0.1 i.e.,

$$U_1 = -.4$$
 $U_i = U_{i-1} + 0.1$ $i = 2, 3, ...50$
(D2)

and the next 50 points are given by

$$U_i = U_{i-1} + 0.25$$
 $i = 51, 52, ...100$ (D3)

Energies associated with these lethargies are given by $\mathbf{E_i} = \mathbf{E_5} \ \mathbf{e^{-U}i}.$

GRCUP	ENERGY I	NTERVAL(E.V.)	LETHARGY INTERVAL

APPENDIX E

Structure of the Data Tapes

Tables XIII and XIV of this appendix show the structure of the two data tapes used in New Barnyard. Table XV lists explanations for some parts shown in Tables XIII and XIV.

If one desires to use either of these data tapes in a new computer code, he should study these tables carefully.

TABLE XIII

Structure of the GGC-4 Data Tape

Record	Number of Words	<u>Variable</u> *	Description
1	3	NTID(1) = NBT	Tape identification number.
		NTID(2) = NEP	Number of fast energy boundaries (groups + 1). (Note #1)
		NTID(3) = NGT	Number of thermal energy points. (Note # 2)
2	90	AT(1-90)	Tape description (5 lines of 72 characters each).
3	1	LAD = NNOT	Number of nuclides on tape.
	Record 4 is records 4 =		ch nuclide (number of
4	21	ESS(1-18) = DAD (1-18)	Nuclide description.
		ESS(19-21)= DAD (19-21)	Nuclide I.D. number, number of resolved resonances, number of unresolved resonances.
5	4	LEN(1)	Resonance data. (Note #3)
		LEN(2)	Resonance data. (Note #3)
		LEN(3)	Resonance data. (Note #3)
		LBS = LEN (4)	Resonance data. (Note #3)
6	LBS (max. = 5101)		Resonance data. (Note #3)
7	NELT = NEP + 2 NEP + 1)		Fast energy group boundaries (NEP+1 values), fast lethargy boundaries (NEP+1 values), fast lethargy intervals (NEP values).
8	NGT	TTT (1-NGT)	Thermal energy points. (Note #2)

^{*} The variable names that appear in the GGC-4 Source deck are listed in this column. This tape is written in binary and no Format statements are required when "reading in" these variables.

TableXIII(Contd')

Record	Number of Words	Variable	Description
9	1	NSP	Number of fission spectra
		s repeated for e rds 10 = NSP).	on tape. ach fission spectrum (num-
10	LNR=17+NEP	ESS (1-18)	Description of fission source spectrum.
		ESS (19-LNR)	Fission source spectrum for each fast energy group. (Note #4)
11	1	MRESN	Number of nuclides with resonance data.
			ted for each resonance 12 and 13 = MRESN).
12	3	SS(13)	Nuclide I.D. number. (Note #5)
		SS(14)	Resonance data.(Note #3)
		SS(15)	Resonance data. (Note #3)
13	LT=6*SS(14)+ SS(15) + 9	TT(1-LT)	Resonance data for nuclide.
	Records 14	through 25 are r	epeated for each nuclide.
14	37	ESS(1-18)	Nuclide description.
		SS(13)	Nuclide I.D. number
		SS(14)	Resonance data. (Note #3)
		SS(15)	Resonance data. (Note #3)
		SS(16)	Length of PO array (same length for P1, P2, and P3 arrays). (Note #5)
		SS(17)	Number of groups scattered from PO scattering. (Note #6)
		SS(18)	Number of groups scattered into PO scattering. (Note #7)

TableXIIT(Contd')

Record	Number of Words	<u>Variable</u>	Description
		SS(19-21)	For inelastic array, same as SS(16-18).
		SS(22-24)	For n, 2n array, same as SS(16-18). (Note #8)
		SS(25)	Fission index: non-zero= fissionable nuclide.
		SS(26)=NX	Number of 1-D arrays (absorption, fission, etc.)
		SS(27-29)	For total scatter array, same as SS(16-18).
		SS(30)	Number of records for this nuclide.
		SS(31)	Mass number of nuclides.
	If number of 1-D present.	arrays [SS(26)]	is zero, record 15 not
15	IMX=(6+NEP)NX	TTT(1-IMX)	One-dimensional cross- section arrays in form: type number (1=absorption, 2=fission, etc.), descrip- tion (5 words), cross-sec- tion for each energy group. (Note #9)
	Records 16 throug SS(16) is zero.	h 19 not present	if length of PO array
16	IDK=SS(16)	TTT(1-IDK)	PO scattering array in form: $\sigma 1 \rightarrow 1$, $\sigma 1 \rightarrow 2$, $\sigma 1 \rightarrow 3$, $\sigma 2 \rightarrow 2$, $\sigma 2 \rightarrow 3$,, $\sigma 3 \rightarrow 4$, (Note #10)
17	IDK	TT(1-IDK)	P1 scattering array (same form as P0. (Note #11)
18	IDK	TT(1-IDK)	P2 scattering array (same form as P0). (Note #11)
19	IDK	TT(1-IDK)	P3 scattering array (same form as P0). (Note #11)

Table XIIContd')

	Record 16 is established.	repeated until the	entire P7 array is
17	21	A(I), I=1,21 Format (9A4,A1,10A4,A3)	Description of the P8 data that follows

TABLE XIV(Contd')

Record	Number of Words	<u>Variable</u>	Description	
18	12	M(K), TEMP(K), K=1,6 Format (6(I2,1X,E9.0))	The P8 elastic scattering transfer microscopic cross sections	
	Record 18 is repeated until the entire P8 array is established.			
	Records 1 thm	cough 18 are repeate	ed for each nuclide.	

TABLE XV

Comments About the Data Tapes

Note Number	Comments
1	NEP is equal to one more than the number of fine groups. This number is 100 for a 99 group data tape.
2	This information is for a thermal spectrum calculation and is not used in the GGC-4 source deck.
3	The resonance data included on this tape is not used; therefore, no effort is made to describe it.
4	The fission spectrum for each fine group is given as the fractional number of fission neutrons born in that group, i. Thus,
	$\sum_{i=1}^{99} \chi_{i} = 1.000.$
5	SS(16) is the total length of the PO elastic transfer array. The P1, P2, and P3 arrays are the same length as that for PO.
6	SS(17) is the number of incident energy groups, and is equal to 99.
7	SS(18) is the maximum number of secondary energy groups for which elastic transfer cross sections are given. This number includes the in-group term.
8	SS(19) through SS(24) are values similar to those given for elastic scattering. Note: no P1, P2, or P3 arrays are given for inelastic or (n,2n) scattering.

TABLE XV (Contd') Note Number Comments 9 The I-D arrays have been given a numeric identification: I.D. Number Description of Reaction 1 Absorption (the fission cross section plus any other neutron removing reaction). 2 Fission cross section. 3 Nu,)/, the average number of fission neutrons produced per fission event (includes delayed neutrons). 4 (n,χ) radiative capture 5 (n, p) 6 (n, α) 7 (n, d) 8 (n, t) 9 (n, n)p(n, n) d 10 11 (n, n) t (The I-10 arrays are given in sequential order.) The elastic PO scattering cross sections are 10 given as a continuous array. The order of giving the cross sections is $\mathcal{O}_{1 \to 1}^{\text{elas}}$, $\mathcal{O}_{1 \to 2}^{\text{elas}}$, $\mathcal{O}_{1 \longrightarrow 3}^{\text{elas}}, \ldots, \mathcal{O}_{1 \longrightarrow [1 + \text{SS}(18) - 1]}^{\text{elas}}, \mathcal{O}_{2 \longrightarrow 2}^{\text{elas}}, \mathcal{O}_{2 \longrightarrow 3}^{\text{elas}},$

 $O_{1\rightarrow 3}, \ldots, O_{1\rightarrow [1+SS(18)-1]}, O_{2\rightarrow 2}, O_{2\rightarrow 3},$ elas $2\rightarrow [2+SS(18)-1], O_{3\rightarrow 3}, O_{3\rightarrow 4}, \ldots,$ $O_{3\rightarrow [3+SS(18)-1]}, O_{3\rightarrow 3}, O_{3\rightarrow 4}, \ldots,$

TABLE XV (Contd')

Note Number

Comments

$$\sigma_{N\to N}^{\text{elas}}, \sigma_{N\to N+1}^{\text{elas}}, \ldots, \sigma_{N\to [N+SS(18)-1]}^{\text{elas}},$$

These cross sections are given in units of barns. There are SS(16) total terms in this array. The elastic P1, P2, P3 arrays are given in exactly the same manner.

- Recall PN = $(2N+1)*OSN(i\rightarrow j)$; therefore, P1 = $3*Osl(i\rightarrow j)$, P2 = $5*Os2(i\rightarrow j)$, etc. The values listed on the tape are the PN values and not the $O_{sn}(i\rightarrow j)$ values.
- The inelastic and (n, 2n) scattering arrays are given in the same manner as the PO elastic arrays. However, the number of groups scattered is generally taken to be 100 for these reactions, thus for the inelastic scattering array, the cross sections are given as:

For a 99 group library tape there is a low energy "dump" group (#100). This group represents the cross sections scattered to all energies below the low energy boundary of group 99 (0.414 ev).

TABLE XV (Contd')

Note Number	Comments
14	SS(27) is the total size of the total trans- fer array. Since the data tape has 99 fine groups, this number will generally be 5049.
15	The total scattering array for scattering from $i \rightarrow j$ is obtained by
	total scattering PO (elas) inelas n,2n $=$ 0 $+$ 0 $+$ 0 $+$ 2* $=$ 0 $+$ 0 $+$ 2* $=$ 0 $+$ 2 $=$ 0 $+$ 2 $=$ 0 $+$ 2 $=$ 1 $+$ 3 $=$ 2 $+$ 3 $=$ 1 $=$ 1 $=$ 1 $=$ 1 $=$ 1 $=$ 1 $=$ 1 $=$ 1
16	of Scatter for group i is calculated by
	scatter $j=[i+SS(18)-1]$ P0(elastic) j=i $j=i$ j j j j j
17	OP1 scatter for group i is calculated by
	P1 scatter $j=[i+SS(18)-1]$ $0 = \sum_{j=i}^{P1(elastic)} P1(elastic)$
18	An example of this description isMATERIAL NUMBER 1012 100 GROUPS PO
19	These 99 group cross sections are given as \mathcal{O}_1^{ABS} , \mathcal{O}_1 , \mathcal{O}_1 , \mathcal{O}_1 , \mathcal{O}_1 , \mathcal{O}_1 , 99R
	\mathcal{O}_{2}^{ABS} , $\mathcal{O}_{2}^{fission}$, \mathcal{O}_{2}^{total} , $\mathcal{O}_{2\rightarrow2}$, $\mathcal{O}_{1\rightarrow2}$, 98R : \mathcal{O}_{g}^{ABS} , $\mathcal{O}_{g}^{fission}$, \mathcal{O}_{g}^{total} , $\mathcal{O}_{g\rightarrow g}$, $\mathcal{O}_{g}^{-1\rightarrow g}$,

APPENDIX F

99 Group Fission Source Spectrums

99 group fission source spectrums are presented here for the following nuclides:

- (1) U-233
- (2) U-235
- (3) PU-239
- (4) PU-241
- (5) CF-252

This data was taken from pages 42-46 of GA-4265, "GAM-11,

A B₃ code for the calculation of Fast-Neutron Spectra and

Associated Multi Group Constants" by G. D. Joanou and

J. S. Rudek. Each source spectrum has been normalized to 1.

APPENDIX G

Sample Problems

This appendix is devoted to exhibiting New Barnyard output for selected problems. Further explanation of some of the problems is given below. The following is a list of the sample problems included in this appendix:

- (1) Water: 5 group set using GGC-4 source deck (P0 to P3 cross sections included)
- (2) Magnesium: 4 group set using ENDF/B source deck. (P0 to P4 cross sections included.)

 For both of these problems a U-235 source spectrum was used. Each problem has a printout of the input data followed by the cross section output. The output cross section values are identified and they need no explanation here. The printout of the input data is followed by the cross section output. The output cross section values are identified and they need no explanation here. The printout of the input data is included only for convenience of the user. The actual source decks do not print out the data used.

GNE/PHYS 69-8

WATER--5 GROUP SET USING GGC-4 SOURCE DECK

FAST DATA TAPE NUMBER = 31568

TAPE DESCRIPTION....

TAPE I.D. IS 31568.0
THIS TAPE IS GGC4 VERSION OF GGC2 304.0

CONTENTS OF FAST DATA TAPE NUMBER 31568

NUCLIDE NO.		ESCRIPTION
1.0000000	HYDROGEN	
1.2000000	DEUTERIUM	
2.0000000	HELIUM	
3.0062000	LITHIUM-6	ENDF/B DATA AUGUST 1967
3.0072000	LITHIUM-7	ENDF/B DATA AUGUST 1967
4.0000000	BERYLLIUM	GA-5905
5.0000000	BORON NATUR	RAL
5.0100000	BORON	10
6.0200000	CARBON	ENDF/B DATA JULY 1967
7.0000000	NITROGEN	6
8.0200000	OXYGEN	ENDF/B OCTOBER 1967
11.0000000	SODIUM	
12.0000000	MAGNESIUM	
13.0000000	ALUMINUM	GA-5884
14.0000000	SILICON	
16.0000000	SULFUR	
20.0000000	CALCIUM	
22.0000000	TITANIUM	
24.0000000	CHROMIUM	
25.0000000	MANGANESE	
26.0000000	IRON	
7.0000000	COBALT	
28.0000000	NICKEL	
9.0000000	COPPER	
2.0000000	MOLYBDENUM

VITA

Bruce D. Green, was born on 16 August 1942, in Portland, Oregon, the son of Sammuel L. Green and Mary J. Green. He graduated from Blackfoot High School, Blackfoot, Idaho, in May 1960 and attended Seattle University, Idaho State University, and then Kansas State University, from which he received the degree of Bachelor of Science in Nuclear Engineering on 15 June 1967. After attending Officer Training School he was commissioned a Second Lieutenant in the USAF on 21 August 1967, and was then assigned to the Air Force Institute of Technology, Resident School of Engineering.

Permanent address: 525 Willard Street Pocatello, Idaho

This thesis was typed by Mrs. Bobbie Thompson.

New Barnyard, a moments code, was neutron macroscopic cross section	written to s. Total, a	calcul	ate multigroup ion, fission, and

New Barnyard, a moments code, was written to calculate multigroup neutron macroscopic cross sections. Total, absorption, fission, and scattering transfer (group to group) cross sections can be calculated. The transport cross section, diffusion coefficient, and the average cosine of the scattering angle can also be calculated for each group. The energy range of these cross sections extends from 14.918 MeV to .4139 eV. Two versions of the moments code were written so that two different data sources could be used. PO through P8 elastic scattering transfer cross sections can be calculated for 20 broad groups.

INSTRUCTIONS

- ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.
- 2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.
- 2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
- 3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.
- 4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
- 5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
- 6. REPORT DATE: Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.
- 7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.
- 8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.
- 9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).
- 10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users
- report directly from DDC. Other qualified users shall request through
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

- 11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.
- 12. SPONSO: ING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.
- 13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.

Unclassified
